Problems set # 3

Physics 303

1. (i) A system initially with volume 10 liters and temperature  $T = 0^{\circ}$ C is compressed adiabatically to a state with volume 5 liters and temperature  $T = 100^{\circ}$ C. In this process, 1000 J of work is done on the system. By how much does the internal energy of the system change in this process? (ii) Instead, we start from the same initial state as above, and end at the same final state as above, by going through the following two steps. Step 1: the system is first heated isochorically (constant volume) to the final temperature  $T = 100^{\circ}$ C. Step 2: the system is then compressed isothermally (constant temperature) to the final volume of 5 liters. In the first step, 800 J of heat had to be added to the system. In the second step, 1900 J of heat flowed out of the system. Compute the energy changes and amounts of work done in each of these two steps. (iii) Can this system be regarded as an ideal gas? Why or why not?

2. The temperature of an ideal gas at initial pressure  $P_1$  and volume  $V_1$  is increased isochorically until the pressure has doubled. The gas is then expanded isothermally (constant temperature) until the pressure drops to its original value. Then it is compressed isobarically (constant pressure) until the volume returns to its initial value. (i) Sketch these processes in the P - V plane and the P - Tplane. (ii) Compute the work done in each process, and the net work done in the cycle, if n = 2kilomoles,  $P_1 = 10^5$  Pa, and  $V_1 = 2$  m<sup>3</sup>.

3. A hypothetical substance has expansivity  $\beta = aT^3/v$  and isothermal compressibility  $\kappa = b/v$ , where a and b are constants. Find the equation of state (including the unknown constant of integration).

4. For stainless steel, the coefficient of linear thermal expansion is  $\alpha = 17.3 \times 10^{-6}/K$  at 20°C, and the bulk modulus is about  $1.6 \times 10^{11}$  Pa. What pressure  $\Delta P$  is needed to keep stainless steel from expanding, when heated from 20°C to 25°C. Assume that the coefficients are constant over this temperature range. Consider the pressure needed on a little steel nugget, to prevent its volume from expanding in any direction. [*Hints:* This question is about expansion in any direction, not just one linear direction: be careful about factors of 3. The isothermal compressibility is the inverse of the bulk modulus.]

5. The pressure on 100 g of nickel is increased quasistatically and isothermally from zero pressure to 500 atm. Calculate the work done on the material, assuming that the density and isothermal compressibility remain constant at the values of  $8.90 \times 10^3$  kg m<sup>-3</sup> and  $6.75 \times 10^{-11}$  Pa<sup>-1</sup>.
